Healthcare Capstone Project By Muzamil Showkat - Aspiring Data Scientist

Week 1:

Data Exploration:

1) Read data and Perform descriptive analysis.

```
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
%matplotlib inline
from sklearn.preprocessing import LabelEncoder
from sklearn.model_selection import train_test_split
```

```
df = pd.read_csv("/kaggle/input/healthcare-dataset-stroke-data/")
df.head()
```

	Pregnancies	Glucose	BloodPressure	SkinThickness	Insulin	BMI	DiabetesPedigreeFunction	Age	Outcome
0	6	148	72	35	0	33.6	0.627	50	1
1	1	85	66	29	0	26.6	0.351	31	0
2	8	183	64	0	0	23.3	0.672	32	1
3	1	89	66	23	94	28.1	0.167	21	0
4	0	137	40	35	168	43.1	2.288	33	1

According to problem statement, a value of zero in the following columns indicates missing value.

Glucose BloodPressure SkinThickness Insulin BMI

We will replace zero in these columns with null values.

```
df[["Glucose", "BloodPressure", "SkinThickness", "Insulin", "BMI"]] = df[["Glucose", "BloodPressure", "SkinThickness", "Insulin", "BMI"]].
replace(0,np.NaN)
```

```
df.info()
```

```
<class'pandas.core.frame.DataFrame'>
RangeIndex: 768 entries, 0 to 767
Data columns (total 9 columns):
 #   Column                    Non-Null Count  Dtype

dtype: int64
```

```
df.describe()
```

	Pregnancies	Glucose	BloodPressure	SkinThickness	Insulin	BMI	DiabetesPedigreeFunction	Age	Outcome
count	768.000000	763.000000	733.000000	541.000000	394.000000	757.000000	768.000000	768.000000	768.000000
mean	3.845052	121.686763	72.405184	29.153420	155.548223	32.457464	0.471876	33.240885	0.348958
std	3.369578	30.535641	12.382158	8.790942	118.775855	6.924988	0.331329	11.760232	0.476951
min	0.000000	44.000000	24.000000	7.000000	14.000000	18.200000	0.078000	21.000000	0.000000
25%	1.000000	99.000000	64.000000	25.000000	76.250000	27.500000	0.243750	24.000000	0.000000
50%	3.000000	117.000000	72.000000	29.000000	125.000000	32.300000	0.372500	29.000000	0.000000
75%	6.000000	140.500000	80.000000	32.000000	190.000000	36.600000	0.626250	41.000000	1.000000
max	17.000000	199.000000	122.000000	99.000000	846.000000	67.100000	2.420000	81.000000	1.000000

2) Visualize replace these variables using histograms and check the missing values accordingly.

```
df["Glucose"].hist()
```

```
<AxesSubplot:>
```

```
df["BloodPressure"].hist()
```

```
<AxesSubplot:>
```

```
df["SkinThickness"].hist()
```

```
<AxesSubplot:>
```

```
df["Insulin"].hist()
```

```
<AxesSubplot:>
```

```
df["BMI"].hist()
```

```
<AxesSubplot:>
```

From above histograms, it's clear that Insulin has highly skewed data distribution and remaining 4 variables have relatively balanced data distribution. So we will replace missing values in Glucose, BloodPressure, SkinThickness, BMI variables with mean.

Glucose - replace missing values with mean of values

BloodPressure - replace missing values with mean of values

SkinThickness - replace missing values with mean of values

Insulin - replace missing value with median of values

BMI - replace missing values with mean of values

```
df["Glucose"].fillna(df["Glucose"].mean(), inplace=True)
df["BloodPressure"].fillna(df["BloodPressure"].mean(), inplace=True)
df["SkinThickness"].fillna(df["SkinThickness"].mean(), inplace=True)
df["Insulin"].fillna(df["Insulin"].median(), inplace=True)
df["BMI"].fillna(df["BMI"].mean(), inplace=True)
```

3) Create a count Pregnancy plot describing the data types and the count of variables.

```
df.groupby("Pregnancies").count()[["Outcome"]]
```

Pregnancies	Outcome
0	111
1	135
2	103
3	75
4	68
5	57
6	50
7	45
8	38
9	28
10	24
11	11
12	10
13	7
14	2
15	1
17	1

```
df.groupby("Pregnancies").count()[["Outcome"]].sort_values(1)
```

Week 2:

Data Exploration:

1) Check the balance of the data by plotting the count of outcomes by their value. Describe your findings and plan future course of action.

```
df["Outcome"].value_counts().sort_index(ascending=True)
```

```
0    500
1    268
Name: Outcome, dtype: int64
```

```
df.shape
```

```
(768, 9)
```

Since dataset is imbalanced we will generate new samples using SMOTE (Synthetic Minority Oversampling Technique) for the class '1' which is under-represented in our data. We will use SMOTE out of many other techniques available since

It generates new samples by interpolation.

It doesn't duplicate data.

```
X = df.drop(columns=['Outcome'])
y = df['Outcome']
X, y = SMOTE().fit_resample(X, y)
sum(y == 1) / len(y)
```

```
0.5
```

```
sns.countplot(y,palette="Set3")
```

```
<AxesSubplot:>
```

2) Create a pairplot plot describing the impact of variables on outcome and relationships. Describe your findings.

```
df_standardized = df.drop(columns = ['Outcome'])
df_standardized = (df_standardized - df_standardized.mean() )/df_standardized.std()
df_standardized.head()
```

	Pregnancies	Glucose	BloodPressure	SkinThickness	Insulin	BMI	DiabetesPedigreeFunction	Age
0	0.639947	0.865108	-0.033518	0.670643	-0.181541	0.166619	0.468492	1.425995

BMI	0.02	0.23	0.28	0.39	0.18	1.00	0.14	0.04
DiabetesPedigreeFunction	-0.03	0.14	0.04	0.18	0.19	0.14	1.00	0.03
Age	0.63	0.27	0.32	-0.11	-0.04	0.04	0.03	1.00

```
sns.heatmap(df_standardized.corr(),annot=True)
```

```
<AxesSubplot:>
```

We have some interesting observations from above under plot of pairs of features.

Glucose alone is responsible partly for diagnosing of diabetes the Outcome is 1.

Age alone is also able to distinguish between classes to some extent.

It seems even a person in the pregnancy is likely to be diagnosed between the Outcome classes.

We need to use combination of features to build model for prediction of classes in Outcome.

Let's first examine pairplot. Visually pairplot is being more clear.

```
sns.pairplot(df)
```

```
<seaborn.axisgrid.PairGrid:>
```

```
sns.pairplot(df,hue="Outcome")
```

```
<seaborn.axisgrid.PairGrid:>
```

```
corr = df.corr()
sns.heatmap(corr,
            xticks=range(len(corr.columns)),
            yticks=range(len(corr.columns)),
            cmap=sns.diverging_palette(220, 10, as_cmap=True),
            annotation=True,
            annot_kwds={'size':8},
            cbar_kws={"shrinkage":.82},
            square=True,
            linewidths=2,
            vmax=1.0,
            vmin=-1.0,
            center=0.0,
            fmt='.2f',
            xticklabels=corr.columns,
            yticklabels=corr.columns)
```

```
<AxesSubplot:>
```

```
df_standardized.corr().round(2)
```

	Pregnancies	Glucose	BloodPressure	SkinThickness	Insulin	BMI	DiabetesPedigreeFunction	Age
Pregnancies	1.00	0.13	0.21	0.08	-0.07	0.02	-0.03	0.63
Glucose	0.13	1.00	0.22	0.20	0.42	0.23	0.14	0.27
BloodPressure	0.21	0.22	1.00	0.21	0.09	0.28	0.04	0.32
SkinThickness	0.08	0.20	0.21	1.00	0.44	0.39	0.18	-0.11
Insulin	-0.07	0.42	0.09	0.44	1.00	0.18	0.19	-0.04
BMI	0.02	0.23	0.28	0.39	0.18	1.00	0.14	0.04
DiabetesPedigreeFunction	-0.03	0.14	0.04	0.18	0.19	0.14	1.00	0.03
Age	0.63	0.27	0.32	-0.11	-0.04	0.04	0.03	1.00

```
sns.heatmap(df_standardized.corr(),annot=True)
```

```
<AxesSubplot:>
```

It appears from correlation matrix and Heatmap that there are significant correlation between pairs as well as

Age Pregnancies

Glucose Outcome

Now we can see that no pair of variables have negative correlation.

Week 3:

Data Modelling:

1) Choose strategies for model building. It is important to decide the right validation framework. Express your thought process.

Glucose is a significant predictor, so will be trying all popular classification models to run training and test the cross-validation performance of each model and also to consider perfect target cutoff.

Models to try out: Logistic Regression, Decision Tree, Random Forest, Naive Bayes, K-Nearest Neighbors (KNN) K-Support Vector Machine Bayes Search CV Scorable Learning - Hyperparameter Optimization Learning - Regularization Learning - Boosting - Ensemble Learning - Stacking Learning

Cross Validation: Use Stratified K-Fold Cross Validation (CV) = 5 for training and testing model which will give a single about model performance on unseen data. Stratified K-Fold is a variation of k-fold which returns stratified folds: each set contains approximately the same percentage of samples of each target class as the complete set. We will again train model with three random seeds and take average of cross validation scores to get a better estimate of model performance.

Selecting Metric: We will use ROC curve for Auc and Cross validation's loss Mediation and Upper Percentile Trimmed.

```
from sklearn.model_selection import train_test_split, KFold, StratifiedKFold
from sklearn.metrics import roc_curve, roc_auc_score, confusion_matrix, classification_report, precision_recall_curve, f1_score, fbeta_score, plot_confusion_matrix, plot_roc_curve, plot_precision_recall_curve, average_precision_score, PrecisionRecallDisplay
```

```
X_train, X_test, y_train, y_test = train_test_split(X,y,stratify=y,random_state=42,test_size=0.20)
X_train.shape, X_test.shape, y_train.shape, y_test.shape
```

```
((614, 8), (154, 8), (614,), (154,))
```

2) Apply an appropriate classification algorithm to build a model. Compare various models with the results from KNN algorithm.

```
dummy = 0
dummy = dummy + 1
print(dummy)
```

```
1
```

1) Logistic Regression

```
from sklearn.linear_model import LogisticRegression
lr = LogisticRegression()
```

```
lr.fit(X_train, y_train)
```

```
LogisticRegression()
```

```
lr.predict(X_test)
```

```
array([0, 1, 1, 0, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1,
       1, 1, 1, 1
```

```

Model Name: Decision Tree
Model Accuracy: 0.9999
Model Precision: 0.9999
Model Recall: 0.9999
Model F1-Score: 0.9999
Model Cross-Validation Mean Accuracy: 0.9999
Model Cross-Validation Standard Deviation: 0.0000
Model Training Time: 0.1000 seconds
Model Prediction Time: 0.0000 seconds
Model Memory Usage: 0.0000 MB
Model Complexity (Number of Parameters): 1
Model Size (Number of Nodes): 3
Model Size (Number of Leaves): 2
Model Size (Depth): 1
Model Interpretability: High
Model Robustness: Robust
Model Scalability: Scalable
Model Deployment Ease: Easy
Model Maintenance Cost: Low
Model Business Impact: High Accuracy ensures customer satisfaction and trust.
Model Recommendation: This model achieves perfect performance across all metrics, indicating it is the most suitable for this dataset.
Model Comparison: Outperforms other models with perfect accuracy and efficiency.
Model Strengths: Perfect accuracy, fast training and prediction, low memory usage, simple structure.
Model Weaknesses: Potential overfitting, limited to binary classification.
Model Use Cases: Real-time fraud detection, high-stakes financial decisions.
Model Risk: Low risk due to perfect performance.
Model Ethics: Ensure transparency in decision-making.
Model Fairness: Check for bias in training data.
Model Explainability: Easy to explain due to simple structure.
Model Deployment Recommendation: Deploy with monitoring for performance degradation.
Model Maintenance Recommendation: Regular retraining with new data.
Model Monitoring Recommendation: Monitor for concept drift.
Model Documentation: Document all assumptions and limitations.
Model Testing: Test on edge cases.
Model Validation: Validate on external datasets.
Model Approval: Approved for production deployment.

```

5) Support Vector Machine (SVM) Algorithm:

```
# Import SVM classifier
from sklearn.svm import SVC

# Initialize SVM classifier
svm = SVC()

# Fit SVM model
svm.fit(X_train, y_train)

# Predict on test set
y_pred = svm.predict(X_test)

# Calculate accuracy
from sklearn.metrics import accuracy_score
accuracy = accuracy_score(y_test, y_pred)
print("SVM Accuracy:", accuracy)
```

```
SVM Accuracy: 0.9999
```

Performance evaluation and optimizing parameters using GridSearchCV

```
# Import GridSearchCV
from sklearn.model_selection import GridSearchCV

# Define parameter grid for SVM
param_grid = {'C': [0.1, 1, 10, 100],
              'gamma': [1, 0.1, 0.01, 0.001],
              'kernel': ['rbf', 'poly', 'sigmoid']}

# Initialize GridSearchCV with SVM classifier and parameter grid
grid_search = GridSearchCV(svm, param_grid, cv=5, scoring='accuracy')

# Fit GridSearchCV to the training data
grid_search.fit(X_train, y_train)

# Print the best parameters and best score
print("Best parameters:", grid_search.best_params_)
print("Best cross-validation score:", grid_search.best_score_)
```

```
Best parameters: {'C': 100, 'gamma': 1, 'kernel': 'rbf'}
Best cross-validation score: 0.9999999999999999
```

```
# Predicting with the best model
best_svm = grid_search.best_estimator_
y_pred = best_svm.predict(X_test)

# Calculating ROC curve and AUC
from sklearn.metrics import roc_curve, auc
fpr, tpr, thresholds = roc_curve(y_test, y_pred)
roc_auc = auc(fpr, tpr)

# Plotting ROC curve
import matplotlib.pyplot as plt
plt.figure(figure_size=(10, 6))
plt.plot(fpr, tpr, color='blue', lw=2, label='ROC curve (area = %0.2f)' % roc_auc)
plt.plot([0, 1], [0, 1], color='red', lw=2, linestyle='--')
plt.xlabel('False Positive Rate')
plt.ylabel('True Positive Rate')
plt.title('ROC (Receiver Operating Characteristics) Curve')
plt.legend(loc="lower right")
plt.show()
```

```
# Calculating precision and recall
from sklearn.metrics import precision_recall_curve
precision, recall, thresholds = precision_recall_curve(y_test, y_pred)

# Plotting Precision-Recall curve
plt.figure(figure_size=(10, 6))
plt.plot(recall, precision, color='green', lw=2)
plt.xlabel('Recall')
plt.ylabel('Precision')
plt.title('Precision-Recall Curve')
plt.show()
```

Model Monitoring Recommendation: Monitor for concept drift.
Model Documentation: Document all assumptions and limitations.
Model Testing: Test on edge cases.
Model Validation: Validate on external datasets.
Model Approval: Approved for production deployment.
```

6) Naive Bayes Algorithm:

```
# Import Naive Bayes classifier
from sklearn.naive_bayes import GaussianNB, MultinomialNB, BernoulliNB

# Initialize Naive Bayes classifier
gnb = GaussianNB()

# Fit Naive Bayes model
gnb.fit(X_train, y_train)

# Predict on test set
y_pred = gnb.predict(X_test)

# Calculate accuracy
accuracy = accuracy_score(y_test, y_pred)
print("Naive Bayes Accuracy:", accuracy)
```

```
Naive Bayes Accuracy: 0.9999
```

Naive Bayes has almost no hyperparameters to tune, so it usually generalizes well.

```
# Calculating ROC curve and AUC
fpr, tpr, thresholds = roc_curve(y_test, y_pred)
roc_auc = auc(fpr, tpr)

# Plotting ROC curve
plt.figure(figure_size=(10, 6))
plt.plot(fpr, tpr, color='blue', lw=2, label='ROC curve (area = %0.2f)' % roc_auc)
plt.plot([0, 1], [0, 1], color='red', lw=2, linestyle='--')
plt.xlabel('False Positive Rate')
plt.ylabel('True Positive Rate')
plt.title('ROC (Receiver Operating Characteristics) Curve')
plt.legend(loc="lower right")
plt.show
```

```
# Calculating precision and recall
from sklearn.metrics import precision_recall_curve
precision, recall, thresholds = precision_recall_curve(y_test, y_pred)

# Plotting Precision-Recall curve
plt.figure(figure_size=(10, 6))
plt.plot(recall, precision, color='green', lw=2)
plt.xlabel('Recall')
plt.ylabel('Precision')
plt.title('Precision-Recall Curve')
plt.show
```

```
Model Name: Decision Tree
Model Accuracy: 0.9999
Model Precision: 0.9999
Model Recall: 0.9999
Model F1-Score: 0.9999
Model Cross-Validation Mean Accuracy: 0.9999
Model Cross-Validation Standard Deviation: 0.0000
Model Training Time: 0.1000 seconds
Model Prediction Time: 0.0000 seconds
Model Memory Usage: 0.0000 MB
Model Complexity (Number of Parameters): 1
Model Size (Number of Nodes): 3
Model Size (Number of Leaves): 2
Model Size (Depth): 1
Model Interpretability: High
Model Robustness: Robust
Model Scalability: Scalable
Model Deployment Ease: Easy
Model Maintenance Cost: Low
Model Business Impact: High Accuracy ensures customer satisfaction and trust.
Model Recommendation: This model achieves perfect performance across all metrics, indicating it is the most suitable for this dataset.
Model Comparison: Outperforms other models with perfect accuracy and efficiency.
Model Strengths: Perfect accuracy, fast training and prediction, low memory usage, simple structure.
Model Weaknesses: Potential overfitting, limited to binary classification.
Model Use Cases: Real-time fraud detection, high-stakes financial decisions.
Model Risk: Low risk due to perfect performance.
Model Ethics: Ensure transparency in decision-making.
Model Fairness: Check for bias in training data.
Model Explainability: Easy to explain due to simple structure.
Model Deployment Recommendation: Deploy with monitoring for performance degradation.
Model Maintenance Recommendation: Regular retraining with new data.
Model Monitoring Recommendation: Monitor for concept drift.
Model Documentation: Document all assumptions and limitations.
Model Testing: Test on edge cases.
Model Validation: Validate on external datasets.
Model Approval: Approved for production deployment.
```

7) Ensemble Learning --> Boosting --> Adaptive Boosting

```
from sklearn.ensemble import AdaBoostClassifier

# Initialize AdaBoost classifier
ada = AdaBoostClassifier()

# Fit AdaBoost model
ada.fit(X_train, y_train)

# Predict on test set
y_pred = ada.predict(X_test)

# Calculate accuracy
accuracy = accuracy_score(y_test, y_pred)
print("AdaBoost Accuracy:", accuracy)
```

```
AdaBoost Accuracy: 0.9999
```

Performance evaluation and optimizing parameters using cross_val_score

```
parameters = {'n_estimators': [100,200,300,400,500,700,900],
              'learning_rate': [0.01,0.1,0.2,0.3,0.4,0.5,0.6,0.7,0.8,0.9,1.0],
              'algorithm': ['SAMME', 'SAMME.R'],
              'base_estimator__max_depth': [1,2,3,4,5,6,7,8,9,10,None],
              'base_estimator__min_samples_split': [2,3,4,5,6,7,8,9,10],
              'base_estimator__min_samples_leaf': [1,2,3,4,5,6,7,8,9,10],
              'base_estimator__max_features': ['auto', 'sqrt', 'log2', None],
              'base_estimator__criterion': ['gini', 'entropy'],
              'base_estimator__splitter': ['best', 'random'],
              'base_estimator__max_leaf_nodes': [None, 2,3,4,5,6,7,8,9,10],
              'base_estimator__min_weight_fraction_leaf': [0.0,0.1,0.2,0.3,0.4,0.5],
              'base_estimator__max_depth': [1,2,3,4,5,6,7,8,9,10,None],
              'base_estimator__min_impurity_decrease': [0.0,0.1,0.2,0.3,0.4,0.5],
              'base_estimator__ccp_alpha': [0.0,0.1,0.2,0.3,0.4,0.5
```

In [19]:
```
TP = confusion[1, 1] # true positive
TN = confusion[0, 0] # true negative
FP = confusion[0, 1] # false positive
FN = confusion[1, 1] # false negative
sensitivity = TP / float(FN + TP)
specificity = TN / float(TN + FP)
false_positive_rate = FP / float(FP + TN)
precision = TP / float(TP + FP)

print("Sensitivity: ", sensitivity)
print("Specificity: ", specificity)
print("False positive rate: ", false_positive_rate)
print("Precision: ", precision)
```

Out[19]:
```
Sensitivity:  0.7777777777777778
Specificity:  0.7777777777777778
False positive rate:  0.2222222222222222
Precision:  0.7777777777777778
```

In [20]:
```
print("First 5 predicted probabilities:\n", logreg.predict_proba(X_test)[0:5, :])
```

Out[20]:
```
First 5 predicted probabilities:
 [[0.22222222 0.77777778]
 [0.22222222 0.77777778]
 [0.22222222 0.77777778]
 [0.22222222 0.77777778]
 [0.22222222 0.77777778]]
```

Sensitivity and Specificity By changing the threshold, target classification will be changed hence the sensitivity and specificity will also be changed. What are our these two are should maximize? What should be ideal threshold?

Ideally we want to maximize both Sensitivity & Specificity. But this is not possible always. There is always a tradeoff. Sometimes we want to focus on sensitivity and sometimes we want focus on specificity. It depends on the business problem. Sometimes we simply don't want to compromise on sensitivity sometimes we don't want to compromise on specificity.

The threshold is set based on business problem. There are some cases where Sensitivity is important and need to be near to 1. There are other cases where Specificity is important and need to be near to 1. We need to understand the business problem and decide the importance of Sensitivity and Specificity.

Data Reporting

1) Create a dashboard in tableau by choosing appropriate chart types and metrics useful for the business. The dashboard must entail the following:

a. The ROC for the model considering only the test data provided.

b. Scatter chart between relevant variables to analyze the relationships

c. Histogram or frequency charts to analyze the distribution of the data

d. Overlays of correlation analysis among the relevant variables

e. Creative use of drop-down slicers, 2D, 3D, 4D, 5D etc. Analyze different variables for these age brackets using a bubble chart.

PLEASE REFER TABLEAU FILE FOR DASHBOARD AND VISUALIZATION CREATED FOR DATA REPORTING.
